

```

<!--
12
    Develop a PHP program to read the contents of a HTML form
    and display the contents on a browser.

    HTML form file, 12_1_html_form.html
-->
<!--
    Two file approach:
        HTML file for the form, to collect user input
            and then pass it to PHP program
        PHP file to accept(read) variables and values passed to it
-->
<!--
    HTML to read user input ----> PHP to process
                                action = script name/URL
                                HTML      -----> PHP
                                using form input           |   form data appended to the action URL
                                and method = get          |   = post       | sent as the request body
                                = post
                                using HTTP GET POST PUT
-->

<form method="get" action="12_2_disp_user_input.php">
    Department: <input type="text" name="dept" /> <br />
    Semester:   <input type="number" name="sem" /> <br />
    <input type="submit" value="Submit" />
</form>
<!--
    HTML to read user input ----> PHP to process
                                |
                                using HTTP GET POST PUT
                                verify the same, on Firefox
                                Web Developer Tools, F12 , or
                                Ctrl Shift I , or
                                ≡ → More tools → Web Developer Tools
                                and
                                Network (Network Monitor), or Ctrl Shift E
-->
<!--
Based on context, use method="get" , or method="post"
If HTML form uses method="get"
    then, action script, observe URL, http link script?varname=value
If HTML form uses method="post"
    then variable and value sent as part of request body
-->
<!--
